Table 14-2 Electrolyte composition of the human body fluids

Electrolytes	Serum (meq · kg ⁻¹ H ₂ O)	Interstitial fluid (meq · kg ⁻¹ H ₂ O)	Intracellular fluid (muscle) (meq · kg ⁻¹ H ₂ O)
Cations			
Na ⁺	142	145	10
K ⁺	4	4	156
Ca ²⁺	5		3
Mg ²⁺	2		26
Totals	153	149	195
Anions			
Cl ⁻	104	114	2
HCO ₃ ⁻	27	31	8
HPO ₄ ²⁻	2		95
SO ₄ ²⁻	1		20
Organic acids	6		
Proteins	13		55
Totals	153	145	180

Note: Some of the ions contained within cells are not completely dissolved within the cytosol, but may be partially sequestered within cytoplasmic organelles. Thus, the true free Ca²⁺ concentration in the cytosol is typically below the overall value given in the table for intracellular Ca²⁺. Failure of anion and cation totals to agree reflects incomplete tabulation.

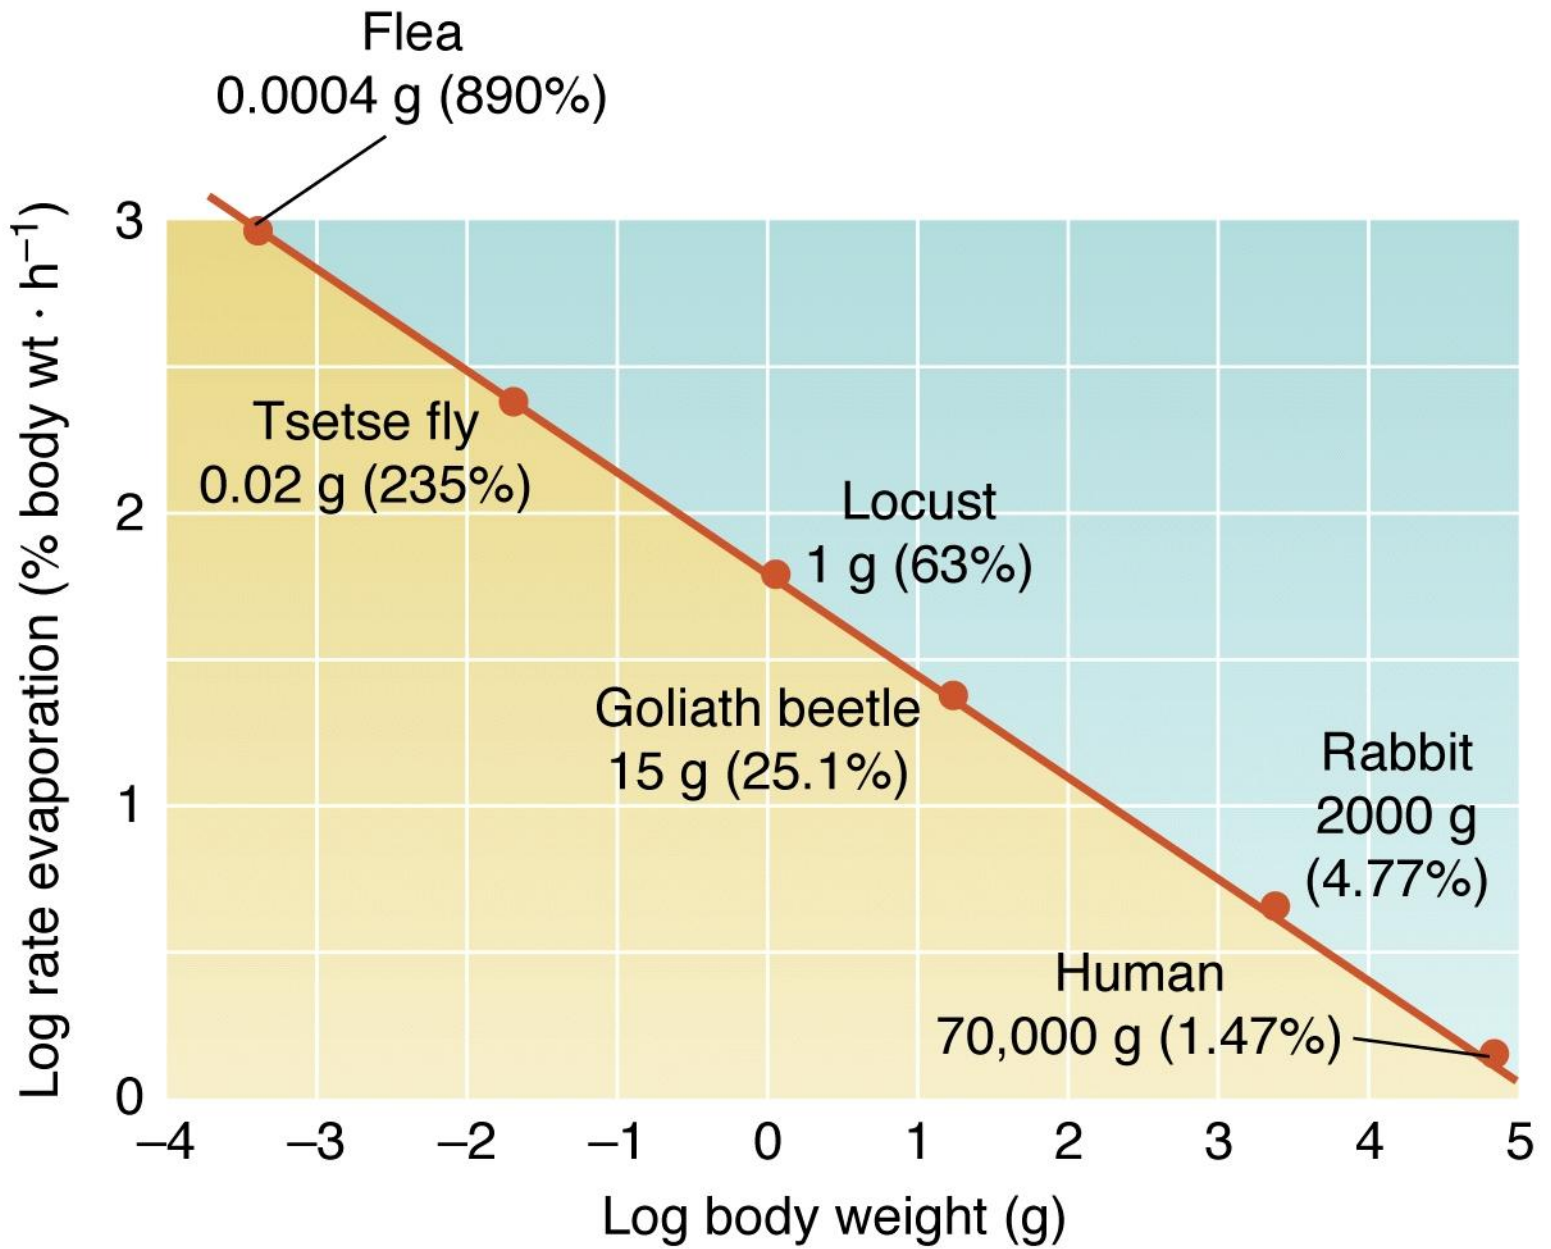

Table 14-3 Evaporative water loss of representative animals under desert conditions

Species	Water loss ($\text{mg} \cdot \text{cm}^{-2} \cdot \text{h}^{-1}$)	Remarks*
Arthropods		
<i>Eleodes armata</i> (beetle)	0.20	30°C; 0% r.h.
<i>Hadrurus arizonensis</i> (scorpion)	0.02	30°C; 0% r.h.
<i>Locusta migratoria</i> (locust)	0.70	30°C; 0% r.h.
Amphibians		
<i>Cyclorana alboguttatus</i> (frog)	4.90	25°C; 100% r.h.
Reptiles		
<i>Gehrydra variegata</i> (gecko)	0.22	30°C; dry air
<i>Uta stansburiana</i> (lizard)	0.10	0°C

* r.h. stands for relative humidity. Where not indicated, relative humidity is not available.

† The cactus mouse and African oryx are desert animals and employ various water-conservation measures. Thus their evaporative water loss is much less than that of humans.

Source: Hadley, 1972.

Table 14-3 Evaporative water loss of representative animals under desert conditions

Species	Water loss ($\text{mg} \cdot \text{cm}^{-2} \cdot \text{h}^{-1}$)	Remarks*
Birds		
<i>Amphispiza belli</i> (sparrow)	1.48	30°C
<i>Phalaenpitus nutallii</i> (poorwill)	0.86	30°C
Mammals†		
<i>Peromyscus eremicus</i> (cactus mouse)	0.66	30°C
<i>Oryx beisa</i> (African oryx)	3.24	22°C
<i>Homo sapiens</i>	22.32	70 kg; nude, sitting in sun; 35°C

* r.h. stands for relative humidity. Where not indicated, relative humidity is not available.

1

Micropipette is inserted and oil is injected until it enters proximal tubule.

2

Perfusion fluid is injected in oil column, forcing oil droplet forward to end of tubule.

3

After 20 minutes, second fluid forces a second oil droplet forward, driving perfusion fluid forward.

Ability of the tubule segment to reabsorb or secrete substances is determined by comparing composition of perfusate before and after injection.

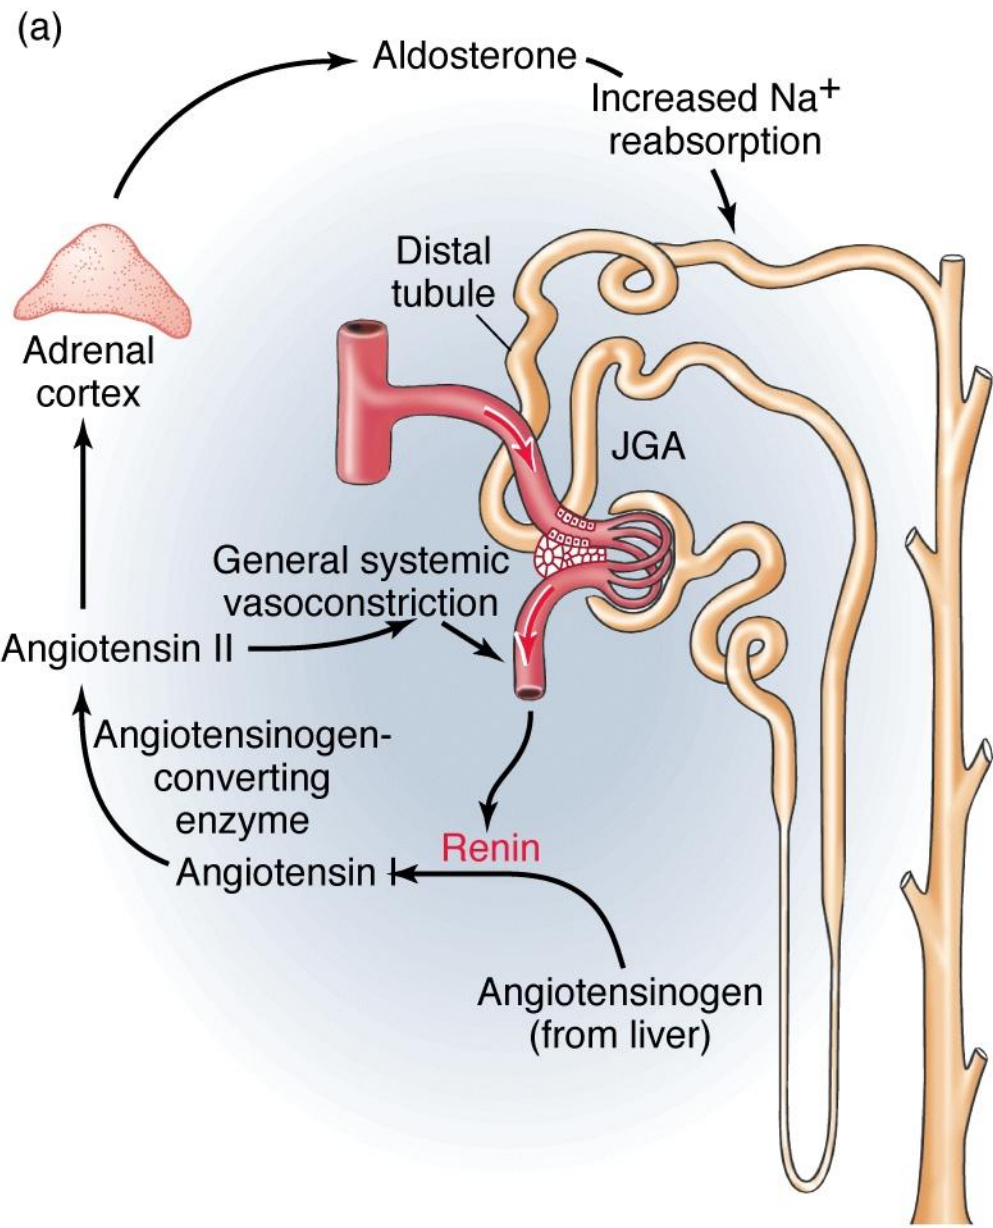

Ability of the tubule segment to reabsorb or secrete substances is determined by comparing composition of perfusate before and after injection.

Transfer to seawater

Time (days)

Table 14-10 Physiological acclimatizations that accompany the movement of fish to water of differing salinity

(A) From freshwater to seawater

1. The proton pump that powers active uptake of NaCl is down-regulated.
 2. The rise in the flux of Na⁺ into the body raises plasma Na⁺, stimulating an increase in plasma cortisol and growth hormone levels.
 3. Hormones induce the proliferation of chloride cells and an increase in the infolding of their basolateral membranes.
 4. The changes above cause an increase in the activity of the Na⁺/K⁺ pump and the secretion of NaCl.
 5. Plasma Na⁺ levels return to normal.
-

Table 14-10 Physiological acclimatizations that accompany the movement of fish to water of differing salinity

(B) From seawater to freshwater

1. The paracellular gaps between chloride and accessory cells close in response to low external Na^+ levels, causing NaCl efflux to fall rapidly.
 2. Plasma prolactin levels increase.
 3. Prolactin causes the number of chloride cells to decrease and the apical pits to disappear.
 4. As a result, the activity of the Na^+/K^+ pump falls.
 5. Up-regulation of the proton pump returns the fish to the freshwater condition.
